

## Experiment 12.2 Calorimetry

Hypothesis We can use what we know about water to measure the specific heat capacity of a metal object

### Procedure

1. Heat  $\frac{1}{4}$  of a mug of water on a burner.
2. Weigh the hex nut ( $m_{\text{metal}}$ ) to the nearest gram.
3. Place the hex nut in the water on the burner.
4. Place one Styrofoam cup within another to make a calorimeter.
5. Weigh the empty calorimeter ( $m_{\text{calorimeter}}$ ).
6. Add enough cold water to the calorimeter so when you add the hex nut later it will be fully submerged.
7. Weigh the calorimeter with the water ( $m_{\text{calorimeter} + \text{water}}$ ).
8. Measure the temperature of the water in the calorimeter to the tenth of a degree ( $T_{\text{initial}}$ ).
9. When the water in the mug boils, use tongs to remove the hex nut and carefully place in the calorimeter
10. Note the maximum temperature ( $T_{\text{final}}$ ) to the tenth of a degree of the calorimeter water as it heats up from the hex nut.

### Observations

$m_{\text{metal}} = \text{_____ g}$  (mass of the hex nut)

$m_{\text{calorimeter}} = \text{_____ g}$  (mass of the empty cups)

$m_{\text{calorimeter} + \text{water}} = \text{_____ g}$  (mass of the cups and cold water)

### Temperature increase of the water

$T_{\text{initial}} = \text{_____ } ^\circ\text{C}$  (temperature of the cold water to begin with)

$T_{\text{final}} = \text{_____ } ^\circ\text{C}$  (temperature of the cold water after the hex nut was added)

### Temperature decrease of the metal

$T_{\text{initial}} = \text{_____ } ^\circ\text{C}$  (temperature of the hex nut in boiling water)

$T_{\text{final}} = \text{_____ } ^\circ\text{C}$  (temperature of the hex nut after it has cooled down in the water)

## Calculation

1. How much warmer did the water in the calorimeter become?

Find the temperature change of the water ( $\Delta T_{\text{water}}$ ) using  $\Delta T_{\text{water}} = T_{\text{final}} - T_{\text{initial}}$

$$\Delta T_{\text{water}} = \text{_____ } ^\circ\text{C} - \text{_____ } ^\circ\text{C}$$

$$\Delta T_{\text{water}} = \text{_____ } ^\circ\text{C}$$

2. How much colder did the hex nut become?

Find the temperature change of the metal ( $\Delta T_{\text{metal}}$ ) using  $\Delta T_{\text{metal}} = T_{\text{final}} - T_{\text{initial}}$ . Remember, the object **started** in boiling water at 100 °C, and cooled to the same  $T_{\text{final}}$  for water.

$$\Delta T_{\text{metal}} = \text{_____ } ^\circ\text{C} - \text{_____ } ^\circ\text{C}$$

$$\Delta T_{\text{metal}} = \text{_____ } ^\circ\text{C}$$

3. What is the mass of the water in the calorimeter (two cups)?

$$m_{\text{water}} = m_{\text{calorimeter+water}} - m_{\text{calorimeter}}$$

$$m_{\text{water}} = \text{_____ } \text{g} - \text{_____ } \text{g}$$

$$m_{\text{water}} = \text{_____ } \text{g}$$

4. How much energy did the water absorb from the heated hex nut?

Calculate the energy absorbed by the water ( $q_{\text{water}}$ ) from the cooling metal object using  $q = mc\Delta T$

$$q_{\text{water}} = m_{\text{water}} \times c_{\text{water}} \times \Delta T_{\text{water}} \quad \text{and} \quad (c_{\text{water}} = 4.184 \text{ J/g}^\circ\text{C})$$

$$q_{\text{water}} = \text{_____ } \text{g} \times \text{_____ } \text{J/g}^\circ\text{C} \times \text{_____ } ^\circ\text{C}$$

(use the numbers you've calculated in the previous steps for  $m_{\text{water}}$  and  $\Delta T_{\text{water}}$ )

$$q_{\text{water}} = \text{_____ } \text{J}$$

5. How much energy did the hex nut release into the water and the calorimeter? You can calculate that with this formula,  $-q_{\text{metal}} = q_{\text{water}} + q_{\text{calorimeter}}$  because the energy **lost** by the metal is **absorbed** by the water and calorimeter. Furthermore, since the calorimeter is a light, well insulated cup, the energy it absorbed ( $q_{\text{calorimeter}}$ ) is negligible (i.e. 0), so the energy the water absorbed is the same amount as the hex nut released or **lost**.

$$\text{So: } q_{\text{calorimeter}} = 0,$$

$$\text{therefore, } -q_{\text{metal}} = q_{\text{water}} + 0$$

$$\text{Or: } q_{\text{metal}} = -q_{\text{water}}$$

$$\text{Therefore: } q_{\text{metal}} = - \text{_____ } \text{J} \quad (\text{substituting } q_{\text{water}} \text{ from step 4})$$

6. So, what is the specific heat capacity of the hex nut ( $c_{\text{metal}}$ )?

To find out what the specific heat capacity ( $c_{\text{metal}}$ ) is, use  $q = mc\Delta T$ , and rearrange the formula so it reads  $c_{\text{metal}} = \dots$

- Divide both sides of  $q = mc\Delta T$  by  $m\Delta T$
- Cancel the  $(m\Delta T) / (m\Delta T)$  on the right hand side to leave  $c$

$$c_{\text{metal}} = \frac{q_{\text{metal}}}{m_{\text{metal}}\Delta T_{\text{metal}}}$$

Now insert into this formula the values you calculated for  $q_{\text{metal}}$  (the energy **lost** by the hex nut) and  $\Delta T_{\text{metal}}$ , and your measurement of  $m_{\text{metal}}$ :

$$c_{\text{metal}} = \left( \frac{\text{J}}{\text{g}(\text{ }^\circ\text{C})} \right)$$

Calculate the answer:

$$c_{\text{metal}} = \text{_____ J/g}^\circ\text{C}$$

Finally, round to the same number of figures as the measurement with the least number of significant figures:

$$c_{\text{metal}} = \text{_____ J/g}^\circ\text{C}$$

(The least precise measurement is the temperature change of the water, which is usually 1 significant figure.)

### Conclusion

The Specific heat capacity of the hex nut was \_\_\_\_\_ J/g $^\circ$ C
